Intravenous immunoglobulin for rheumatic diseases

Record Status
This is a bibliographic record of a published health technology assessment. No evaluation of the quality of this assessment has been made for the HTA database.

Citation

Authors' objectives
Intravenous immunoglobulin (IVIG) therapy is used to provide passive immunity or to alter the immune response by increasing an individual's antibody titer and antigen-antibody reaction potential. IVIG has been investigated as a treatment for patients with rheumatic diseases, with the goals of alleviating symptoms and inducing sustained remissions from disease activity through anti-inflammatory and immunomodulatory effects.

Timeliness warning
