## Subcutaneous implantation of estradiol pellets for postmenopausal disorders

---

### Record Status

This is a bibliographic record of a published health technology assessment. No evaluation of the quality of this assessment has been made for the HTA database.

### Citation

Subcutaneous implantation of estradiol pellets for postmenopausal disorders. Lansdale: HAYES, Inc.. Healthcare Technology Brief Publication. 2010

### Authors' objectives

Menopause, the cessation of menstruation, occurs at around age 50 years for most women. During this process, levels of the hormone estrogen fall dramatically and women may experience hot flashes, sleep disorders, mood swings, vaginal dryness, and decreased sexual desire. In addition, osteoporosis can occur if estrogen levels remain low for prolonged periods. These symptoms can be reduced or prevented by use of hormone replacement therapy (HRT), which typically involves administration of estrogen and progesterone via pills, skin patches, or gels.
